

Western style diet as a risk factor for chronic disease in India Biswadeep Dhar (MS, M.Ed.), LaToya O'Neal (PhD) & Heidi Radunovich (PhD) Department of Family, Youth and Community Sciences, University of Florida.

Objective

- The growing prevalence of obesity worldwide is a major threat, and it has become double burden in many developing and low-income countries.
- This project will further investigate the gaps on understand the role of westernization as a risk factor influencing chronic disease prevalence in the state of West Bengal. The theoretical basis of this research is driven by Arnett's theory of Westernization and by modern concepts of acculturation research

Significance

- To evaluate if sociodemographic (gender) and household characteristics (wealth status) have any impact on chronic disease outcomes with reference to BMI
- To evaluate the relationship between western style diet and how it predicts health behaviors with respect to BMI. This unique and recent nationalized data set from India (NFHS-4) used allows us to address these questions directly.

Methods

- This study will utilize secondary data from a nationalized survey (NFHS-4) in India, particularly from the state of West Bengal (due to the highest prevalence of obesity among adults in India). Sample includes 17668 individuals
- Dependent variable of interest is the body mass index (BMI) indicator of obesity; whereas the independent variable is the western style diet practiced in the state. A multiple linear regression was run to look the mean value of BMI by the level of diet.
- A factorial ANOVA was run to see if gender and wealth status have an impact on BMI.

- * Multiple Linear Regression was done after dummy coding variables; categorical variables of diet components have been transformed to dummy variables.
- * So, as consumption of aerated drinks increase from occasionally to daily, BMI increase by 84.65 units. On the other hand, as consumption of fruits increase; BMI increased by 94.15 units.

- * Here, the interaction effect of Gender and Wealth Index was found to be significant (p<0.01)
 - * Main effects of gender and wealth index were studied and found that wealth index had significant results (p<0.01) meaning that they differ in scores of wealth index groups from poorest to richest. But there were no significant difference between poorer and poorest groups.

Conclusion

- Tukey Honestly Significant Difference (HSD) test showed that richest group differ from all groups of wealth index
- From the plot, it indicates that richer group has the highest mean for females and the richest group has the highest mean for the males. Largest difference between male and female lie in the richest group of wealth index with statistical significance.
- The long-term goal is to reduce the chronic disease rates particularly obesity and to reduce chronic disease disparities among the adults living in the state of West Bengal.
